Article History

Accepted : 15 May 2021 Published : 22 May 2021 Bridges are the structural components that are required for the efficient movement of Trains and locomotives and under earth embankment for crossing of water course like streams across the embankment as road embankment cannot be allowed to obstruct the natural water way. Bridges can be of different shapes such as arch, slab and box. These can be constructed with different material such as masonry (brick, stone etc.) or reinforced cement concrete. Since bridge pass through the earthen embankment, these are subjected to same traffic loads as the road carries and therefore, required to be designed for such loads. The cushion depends on rail profile at the bridge location. For analysis relevant IRCs are required to be referred. The structural elements are required to be designed to withstand maximum bending moment and shear force.

This study provides comparative analysis of a Arch shape stone-concrete (RCC) & General RCC bridge considering IRC loading using analysis tool staad.pro. To determine shear performance of the bridge under vehicular loading.

Keywords : Analysis, bridge, staad.pro, IRC, structure, forces, displacement, stone masonry.

I. INTRODUCTION

Bridges are an important component of all type of modem transport system. In the half of the past decade technical knowledge of earthquake engineering increased considerably. Performances of bridges have vital importance before and after an earthquake event. Hence it must remain functional even after dissipation of seismic event to endure relief as well as security purpose. Substructure of the bridge is more susceptible to damage and its performance must be good during ground motion because substructure connect superstructure to the foundation. Hence failure of substructure leads to collapse of entire bridge which may turn m to disaster. There are many design codes and guidelines available worldwide for the seismic design of bridges. These guidelines are helpful for improving the seismic capacity of the bridges. Despite of many advances made in design of earthquake Resistance Bridge some gaps still remain in many areas due to

unpredictable nature of ground motion. For the analysis of bridges under seismic excitation simplified method (response spectrum method) or time history analysis and pushover analysis are used.

II. LITERATURE REVIEW

Yutao Pang and Li Wu (2018) the research paper investigated the effect of aftershocks on seismic responses of multispan reinforced concrete (RC) bridges using the fragility based numerical approach. For that purpose, a continuous girder RC bridge class containing 8 bridges was selected based on the statistical analysis of the existing RC bridges in China. 75 recorded mainshock-aftershock seismic sequences from 10 well-known earthquakes were selected for the investigation. In order to account for the uncertainty of modeling parameters, uniform design method was applied as the sampling method for generating the samples for fragility analysis. Fragility curves were then developed using nonlinear timehistory analysis in terms of the peak curvature of pier column and displacement of bearings. Finally, the system fragility curves were derived by implementing Monte Carlo simulation on multi-normal distribution of two components.

Results stated that for the RC continuous bridges, the influence of aftershocks can be harmful to both bridge components and system, which increases both the component fragility of the displacement of bearings and seismic curvature of pier sections and system fragility. Additionally, it is better to evaluate the vulnerability of bridge system, rather than only assess the effect of aftershock based on a single component.

Rahul Gangwar et.al (2020) This paper gives the comparative study of R.C.C.(Reinforced Cement Concrete) Girder and P.S.C.(Prestressed Concrete) Girder, which include the design and estimates of R.C.C. and P.S.C. Girder of various spans. The aim of this work is to study R.C.C .girder as well as P.S.C. girder and then compare the results. The idea is to succeed in a superior conclusion regarding the prevalence of the 2 techniques over each other. R.C.C members are commonly used for residential as well as commercial structures and are generally short span. In R.C.C. depth of girder increases with the increase in span due to deflection limitation. To surmise, R.C.C girder shall be suitable for small to medium span however the prevalence of prestressed concrete girder is undeniable for extended spans.

The conclusion derived from the results stated that Reinforced concrete beams are generally heavy. They always need shear reinforcements besides the longitudinal reinforcement for flexure. Prestressed concrete beams are lighter. By providing the curved tendons and the pre-compression, a considerable part of the shear is resisted. In reinforced concrete beams, high strength concrete is not needed. But in prestressed concrete beams, high strength concrete and high strength steel are necessary. Reinforced concrete beams being massive and heavy are more suitable in situations where the weight is more desired than strength. Prestressed concrete beams are very suitable for heavy loads and longer spans. They are slender and artistic treatments can be easily provided. Cracks do not occur under working loads. Even if a minute crack occurs when overloaded, such crack gets closed when the overload is removed. The deflections of the prestressed concrete beams are

small. Prestressed concrete sections are thinner and lighter than RCC sections, since high strength concrete and steel are used prestressed concrete.

Problem Identification

The literature review has suggested that use of a finite element modeling of the Arch Bridges with various material. So it has been decided to use STAAD.Pro for the Finite Element Modeling. With the help of this software study of bridge structure has been done considering Vehicular loading. STAAD.Pro also helps in Finite Element Modeling in view of that different type of forces can apply to get the actual results. In this literature review it is revealed that live project work to implement the same at site and to develop a relation between software and practical work implementation.

Objectives of the study

- 1. To Determine the stability of the structure with considering vehicular load IRC.
- 2. To Determine the variation in structural stability of a structure with stone and reinforced concrete in a arch type bridge geometry.
- 3. To Compare Stone lining RC structure with General RCC structure using analysis tool.

III. Methodology

Step-1: First step is to prepare a literature survey related to bridge, software implementation, vehicle load and structural analysis.

Step-2: second step is to select a geometry and model it in staad.pro.

Fig 2 : Modelling of the bridge

Step-3 To assign section data (concrete and stone) and material properties.

Step-4 To Assign support conditions.

Step-5 To assign vehicle loading and hydraulic data as per provided toposheet.

Step-6: To perform finite element analysis.

Step-7 Assigning Lanes of Deck

V. CONCLUSION

Following are the salient conclusions of this study-

Shear Force

Shear force in known as the unbalance force observed due to transmission of load from beam to column, in our study it is observed that with Arch Bridge it can be minimized in all the cases considered for study.

Axial Force

Axial force is known as the vertical force observe in piers, this force is meant to distribute load from pier to earth. It is observed in the results that with Arch Bridge Distribution of vertical forces can be processed easily.

Bending Moment

In terms of bending moment it is observed that minimum bending is Arch Bridge, which is resulting in comparatively most economical in comparison as bending moment is directly proportional to reinforcement requirement.
