	In order to design an earthquake resistant structure, the analysis of the structure
	G+11 story is done using ETABS 2020.
	G+11 story is analyzed for two different seismic zones, one location at Bhuj
	Gujarat and other location at Jabalpur, Madhya Pradesh and soil types as per IS
	1893:2016. Further the behavior of the structure was investigated for the
	parameters such as Natural period, Displacement, Base shear, Story Stiffness and
	Story Drift.
	Keywords — Base shear, storey displacement, special moment resisting frame,
	static analysis and Etabs.
	their behaviour varies with the type of soil. These

## I. INTRODUCTION

The unique concept used in earthquake engineering is the equivalent lateral force. In structures maximum displacement or member stresses are determined by the Dynamics analysis which further changes to partly dynamic and partly static analysis. There are different types of lateral loads in buildings like wind loads and earthquake loads and their behaviour varies with the type of soil. These types are Hard soil, Medium soil and Soft soil. When seismic waves pass through these soil layers their effects are different .When structure is exhibited to earthquakes it is influenced with the foundation and soil mass. Thus, it changes the movement of the earth .This indicates that the type of soil ,and also depends on the type of structure ,influences the movement of the entire system of ground structures. Because seismic

29

waves are generated from the ground, they consist of changes in the properties of the soil and work in different ways in accordance with the correlate to the properties of the soil. Vibrations that distract the earth's surface caused due to waves generated in the earth are called earthquakes. It is mentioned that earthquakes do not kill human life, but structures that are not built taking into account the forces of an earthquake. Earthquake resistant structures in India currently attach great importance to human life and its security. India's geographical location is such that it comes under the subcontinent area so that's why India is having more than 60% earthquake prone area. Generally buildings are constructed in India design with permanent ,semi – permanent moving loads keeps in mind.

According to IS 1893 2016 code (Clause 6.3.5.3) soil condition is classified into following three types

Type I - Hard Soil: Sand gravel and well graded gravel and sand gravel mixtures without or with clay binder, and poorly graded clayey sands or sand clay mixtures (GB, CW, SB, SW, and SC) having value of N above 30, where N indicates the : standard penetration value.

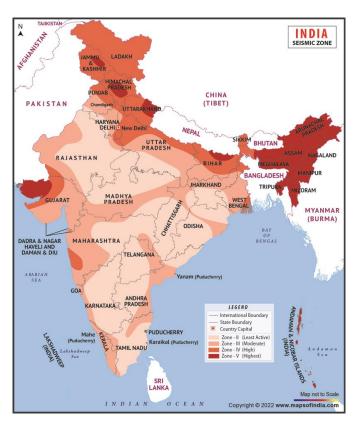

Type II - Medium Soil :All soils having N between 10 and 30, and gravelly sands or poorly graded sands with little or no fines (SP) with N>15.

Type III - Soft Soil :All soils except SP with N

# II. Seismic Analysis

The latest version of seismic zoning map of India given in the earthquake resistant design code of India [IS 1893 (Part 1) 2002] assigns four levels of seismicity for India in terms of zone factors. In other words, the earthquake zoning map of India divides India into 4 seismic zones (Zone 2, 3, 4 and 5) unlike its previous version which consisted of five zones for the country. According to the present zoning map, Zone 5 expects the highest level of seismicity whereas Zone 2 is associated with the lowest level of seismicity. Table I shows the Zone factors.

1 able	e 1 Zone Factor
Z	Zone Factor
Zone Type	Zone Factor
V	0.36
IV	0.24
III	0.16
III	0.1

# Fig 1 Seismic Zone of India Objectives of the Research

- The main goal is to estimate and assess the building's seismic response, then evaluate and design using ETABS considering two different soil condition namely Hard soil and Medium soil.
- G+11 building modelling and application of various loads on ETABS, load calculations

owing to various loading combinations, analysis, and structure design on ETABS.

- Comparison of results of earthquake load applied on the structure for two different zones by ETABS and manual calculations both by an equivalent static method.
- Studying the responses, shear forces, bending moment, seismic forces, and node displacement, and restricting them by applying appropriate properties and materials, then assigning them again.

### III. Literature Survey

Abhishek Mishra et.al (2022) research paper analyzed and compared the seismic response of a G+15 storey RCC frame structure with variable soil conditions (Hard and Soft soil) for seismic Zone IV. Both models were analysed in STAAD Pro V8i software using the Equivalent Static method of seismic analysis and the response of the model was examined in terms of the maximum storey displacement, base shear and story drift.

When compared to both Soft and Hard soil, the base shear value was more in the soft soil. When compared to both soft and hard soil the story drift value is more in the soft soil. The value of storey displacement increases as the stiffness property of the soil stratum decreases, so it was highest for model M1 with soft soil and lowest for model M2 with hard soil.

B. Ramakrishna et.al (2022) research paper aimed to present the analysis of a multi-stored building [G+5] using STAAD Pro by considering different seismic zones for all type of loads (Seismic load, Dead load, Live load and Wind load) and possible load combinations was performed as per Indian codes. The seismic analysis was done under different zones which are Zone-II, Zone-III, Zone-IV, Zone-V and also zone factor values was considered as per IS 18932002 (Part-1). Results were compared on the values of shear, bending moment and deflection for different zones.

Results stated that shear force, bending moment and deflection values for Zone III increased by 60% when compared to Zone II. Shear force, bending moment and deflection values for Zone IV increased by 24% when compared to Zone III. Shear force, bending moment and deflection values for Zone V increased by 50% when compared to Zone IV. For the same loading condition Zone V having more shear force, bending moment and deflection values. As comparing the results zone II having lower shear force, bending moment and deflection values.

Gourav B N et.al (2021) research paper conducted time history, response spectrum and p-delta analyses using Etabs software to study the effects of different soil types and seismic zones for a high-rise building of G+ 30 storey. In the research, a total of 12 models were analyzed for various soils types and seismic zones are systematically compared and discussed for a seismic performance of multistory building. The obtained results were analyzed and compared to determine the most suitable condition for the construction of a given high-rise building to have maximum service life.

Results stated that as the seismicity of the building increases care should be taken by the structural engineers to counter the seismic energy and to safeguard the building. With the change in soil property from hard to medium and from hard to soft the lateral deflection was increased. In Seismic Zone -2, 3 & 5 the values of maximum Shear forces & maximum bending moment are decreasing in hard soil strata when compared with soft soil strata & found the least for the same.

### IV. METHODOLOGY

Step 1: Research paper from different authors are summarized in this section who have focused towards analyzing multi storey high rise structures considering seismic loads with different zones and soil condition Step 2: In order to initiate the modelling of the case study, firstly their's need to initialize the model on the basis of defining display units on metric SI on region India as ETABS supports the building codes of different nations. The steel code was considered as per IS 800:2007 and concrete design code as per IS 456:2000.

Step 3: ETABS provides the option of modelling the structure with an easy option of Quick Template where the grids can be defined in X, Y and Z direction. Here in this case, 5 bays in considered in both X and Y direction with a constant spacing of 4m making the model symmetrical in nature. G+ 11 storey structure is considered with typical storey height of 3.2 m and Bottom storey height of 3.2 m.

### Story Shear in kN

Discussion: Story shear is the graph showing how much lateral (read: horizontal) load, be it wind or seismic, is acting per story. The lower you go, the greater the shear becomes. Story Shear was maximum at 6th Story in both the cases.

Storey Displacement in mm

#### Story Displacement in mm

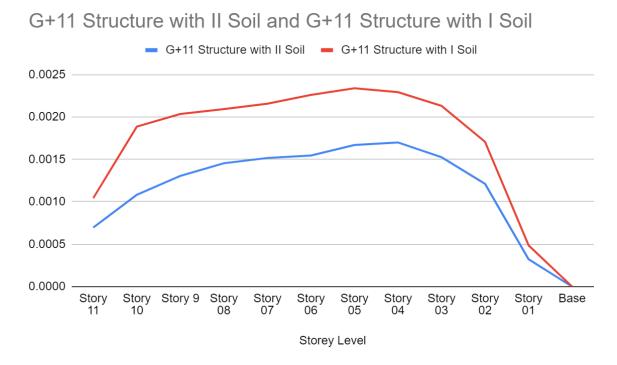

### Story Displacement in mm

Discussion: It is found that with the increase in zones the displacement also increases for each soil type. The maximum value of displacement for hard soil is 8.7,13.9, 20.8, 29.8mm. For medium Soil 11.8, 18.9, 28.3, 42.4mm while for Soft soil it is 13.6, 21.7, 32.6, 48.9mm. It is observed that for zone II to zone III the increment is by around 37% while for zone III t to V the percentage reduces by 22.8%

### Story Drift in m

Discussion: Storey drift is considered as a drift of a particular level with respect to a level below. The above table shows the Zone wise comparison of storey drift with respect to the soil type. The result show that the value of storey drift increases with the increasing zones. It is observed that the Storey drift increases by more than 30% (zone to zone) for symmetric structure for all the soil types.

2.518	3.69	

G+11 Structure with II Soil

Discussion: Model with II soil was least affected in comparison to the other model

#### V. CONCLUSION

From the above results it is concluded that;

### **Base Shear**

"Base Shear is an estimate of the maximum expected lateral force that will occur due to seismic ground motion at the base of a structure". It is observed that the base shear of the building increases with the increasing seismic Zones. Base SHear was maximum for Structure with Soil Type I as 3476.294 kN and 2317.387 kN for structure in II soil type. The seismic response such as base shear for Bhuj earthquake are found to be more by 45.44% than Jabalpur earthquake by using time history analysis.

### Story Displacement

It is found that with the increase in zones the displacement also increases for each soil type. The maximum value of displacement for hard soil is 8.7,13.9, 20.8, 29.8mm. For medium Soil 11.8, 18.9, 28.3, 42.4mm while for Soft soil it is 13.6, 21.7, 32.6,

48.9mm. It is observed that for zone II to zone III the increment is by around 37% while for zone III t to V the percentage reduces by 22.8%. The top story displacement of Jabalpur and Bhuj earthquake by response spectrum method is found to be 33.15% and 34.26% higher.

### Story Drift

Storey drift is considered as a drift of a particular level with respect to a level below. The above table shows the Zone wise comparison of storey drift with respect to the soil type. The result show that the value of storey drift increases with the increasing zones. It is observed that the Storey drift increases by more than 30% (zone to zone) for symmetric structure for all the soil types. The values of the storey drifts for all the stories for all the effects are found to be within the permissible limits specified as per IS: 1893-2002 (Part I).

## VI. Future Scope

- Further research can be extended to different zones of India.
- Further research can even be extended using different analytical tools such as SAP 2000 or STAAD.Pro and identify the most appropriate damping measure to understand the reaction of structure and recommend necessary damping measure.
